(54) Title: UREA DERIVATIVES AS INHIBITORS OF CCR-3 RECEPTOR

(57) Abstract: Urea and thiourea derivatives inhibit cell function of the chemokine receptor CCR-3. These compounds offer an effective means for treating a range of diseases thought to be mediated by the CCR-3 receptor. A variety of useful urea and thiourea derivatives can be synthesized using liquid and solid phase synthesis protocols.

UREA DERIVATIVES AS INHIBITORS OF CCR-3 RECEPTOR

BACKGROUND OF THE INVENTION

The present invention relates to certain urea derivatives that are inhibitors of CCR-3 receptor activity, methods for preparing these compounds, pharmaceutical compositions containing such compounds and methods for their use.

5 Chemokines are chemotactic cytokines that are produced by a variety of cells to attract leukocytes to sites of inflammation or lymphoid tissue. CCR-3 is a chemokine receptor that is expressed in a variety of cells, including, but not limited to, eosinophils, basophils, T cells and dendritic cells. See Ponath, P.D. *et al.*, *J. Exp. Med.* (1996) 183, 2437-2448; Yamada, H. *et al.*, *Biochem. Biophys. Res. Comm.* (1997) 231, 365-368; 10 Sallusto, F. *et al.*, *Science* (1997) 277, 2005-2007; Sato, K. *et al.*, *Blood* (1999) 93, 34-42. CCR-3 is also known as a co-receptor to HIV virus infection. See He, J. *et al.*, *Nature* (1997) 385, 645-649. Several chemokines including eotaxin, eotaxin-2, RANTES, MCP-2, MCP-3, MCP-4 bind to CCR-3 and activate cell functions such as intracellular Ca^{2+} mobilization, chemotactic response, superoxide anion generation and cell aggregation. See 15 Forssmann, U. *et al.*, *J. Exp. Med.* (1997) 185, 2171-2176; Heath, H. *et al.*, *J. Clin. Invest.* (1997) 99, 178-184; Ugucioni, M. *et al.*, *J. Exp. Med.* (1996) 183, 2379-2384; Tenscher, K. *et al.*, *Blood* (1996) 88, 3195-3199; Sato, K. *et al.*, *Blood* (1999) 93, 34-42. In particular, eotaxin exhibits a potent and specific chemotactic activity for eosinophils via binding to CCR-3, *in vitro* and *in vivo*. See Ponath, P. D. *et al.*, *J. Clin. Invest.* (1996) 97, 20 604-612.

Tissue eosinophilia is observed in a number of pathological conditions such as asthma, rhinitis, eczema, inflammatory bowel diseases and parasitic infections. See Bousquest J. *et al.*, *N. Eng. J. Med.* 323, 1033-1039; Middleton, Jr., E. *et al.*, Chapter 42, Allergy Principles and Practice 4th ed. vol.2 Mosby-Year Book, Inc. 1993 U.S.A. In 25 asthma, the airways of patients are infiltrated by a large numbers of eosinophils, and eotaxin production in bronchial mucosa and bronchoalveolar lavage (BALF) is increased.

Several studies have suggested a strong correlation between the number of eosinophils in BALF, the eotaxin level in BALF and the clinical parameters of disease severity. See Walker, C. *et al.*, *J. Allergy Clin. Immunol.* (1991) 88, 935-942; Ying, S. *et al.*, *Eur. J. Immunol.* (1997) 27, 3507-3516. Furthermore, pretreatment with a CCR-3-antibody has
5 been shown to block chemotaxis and Ca^{2+} influx induced by eotaxin, RANTES, MCP-3 or MCP-4, suggesting that most of the eosinophilic response to these chemokines in allergic and eosinophilic patients is mediated through CCR-3. See Heath, H. *et al.*, *J. Clin. Invest.* (1997) 99, 178-184. Similarly, it has recently been disclosed that certain cyclic amine derivatives are antagonistic to CCR-3 and may be useful for treating eosinophil-mediated
10 allergic diseases. See EP 0903349A2. Also, CCR-3 expression on human Th2 type T-cells and human cultured dendritic cells mediates cell functions such as chemotactic response. See Sallusto, F. *et al.*, *Science* (1997) 277, 2005-2007; Sato, K. *et al.*, *Blood* (1999) 93, 34-42. In addition, anti-CCR-3 antibody has been shown to inhibit aggregation of T-cells and dendritic cells, suggesting CCR-3 may regulate the interaction of these cells during the
15 process of antigen presentation. See Sato, K. *et al.*, *Blood* (1999) 93, 34-42. Therefore, CCR-3 inhibitors may also be useful for regulating immune responses.

These examples suggest that CCR-3 mediated diseases may be treated using compounds that inhibit CCR-3 activity. Because CCR-3 is present on many cell types, however, and is responsible for a variety of disease states, an arsenal of compounds which
20 inhibit CCR-3 activity is required to treat CCR-3 mediated diseases effectively.

25 mediated diseases.

20 The compounds of the present invention can be prepared by various methods including, but not limited to, liquid phase or a solvent based synthesis and solid phase synthesis involving a polymeric resin.

The liquid phase synthesis generally involves addition of a substituted or unsubstituted alkyl amine containing compound to a protected amine containing starting 25 material bearing a leaving group (e.g., Cl, Br, I, OTs, OMs, etc.). The resulting product bearing a protonated amine is reacted with an alkyl halide to yield a substituted amine. Then, the protected amine moiety is deprotected by addition of base or e.g., hydrazine.

The resultant free amine is reacted with a compound containing an aromatic isocyanate to yield the aromatic urea derivative.

A second synthesis involves the reaction of aromatic isocyanate with a haloalkylamine. The resultant product is then further reacted with an optionally substituted amine containing compound, the amine of the optionally substituted amine containing
5 compound is substituted by reaction with an alkyl halide to yield the aromatic urea derivative.

An additional method that can be used to prepare the present compounds involves reaction of a protected amine containing starting compound with an alkylamine. The
10 resultant diamine is reacted with an ester containing a leaving group, after deprotection, the aromatic urea derivative is formed by reaction with a compound containing an aromatic isocyanate.

The aromatic urea derivatives can be further derivatized by conventional organic synthesis techniques, for example, an ester can be converted to an acid by addition of a
15 metal hydroxide. Additionally, salts of the compounds can be formed by conventional synthetic techniques, such as addition to an amine moiety to form an ammonium salt.

Solid phase synthesis involves the use of polymeric resins. Reductive amination of the linker to the resin occurs by reacting a haloalkylamine with the polymeric resin. The protonated amine is then protected by reaction with a substituted or unsubstituted acid
20 chloride. The halogen of the original haloalkylamine is displaced by reaction with an alkyl amine compound and reductive amination follows by reaction with an aldehyde. The protected amine is deprotected by reaction with, for example, tin chloride, an acid or an amine. The deprotected amine is subsequently reacted with an isocyanate to yield the urea moiety, the product is isolated by working up the reaction mixture, for example, in HCl
25 gas.

In one embodiment of the present invention, an effective amount of a pharmaceutical composition comprising one or more of the disclosed compounds is administered to a patient suffering from CCR-3 mediated disease. The active compound of the pharmaceutical composition can be administered in a variety of forms, including, but not
30 limited to a salt, a hydrate or a prodrug. In addition, the pharmaceutical composition can optionally contain suitable carriers or excipients.

A "pharmaceutical composition" refers to a mixture of one or more of the compounds described herein, or pharmaceutically acceptable salts, hydrates or prodrugs thereof, with other chemical components, such as physiologically acceptable carriers and excipients. The purpose of a pharmaceutical composition is to facilitate administration of a compound to an organism.

A "prodrug" refers to an agent which is converted into the parent drug in vivo. Prodrugs are often useful because, in some situations, they may be easier to administer than the parent drug. They may, for instance, be bioavailable by oral administration whereas the parent drug is not. The prodrug may also have improved solubility in pharmaceutical compositions over the parent drug.

As used herein, a "physiologically acceptable carrier" refers to a carrier or diluent that does not cause significant irritation to an organism and does not abrogate the biological activity and properties of the administered compound.

An "excipient" refers to an inert substance added to a pharmaceutical composition to further facilitate administration of a compound. Examples of excipients include, but are not limited to, calcium carbonate, calcium phosphate, sugars, starches, cellulose derivatives, gelatin, vegetable oils and polyethylene glycol.

The form of the administered compound depends, in part, upon the use or the route of entry. Such forms should allow the agent to reach a target cell whether the target cell is present in a multicellular host or in culture. For example, pharmacological agents or compositions injected into the blood stream should be soluble in the concentrations used. Other factors are known in the art, and include considerations such as toxicity and forms which prevent the compound or composition from exerting its effect.

A compound of the present invention also can be formulated as a pharmaceutically acceptable salt, e.g., acid addition salt, and complexes thereof. The preparation of such salts can facilitate the pharmacological use by altering the physical characteristics of the agent without preventing its physiological effect. Examples of useful alterations in physical properties include, but are not limited to, lowering the melting point to facilitate transmucosal administration and increasing the solubility to facilitate administering higher concentrations of the drug.

A compound of the present invention can be administered to a mammal, including a human patient, using a variety of techniques. For example, for systemic administration,

oral administration or injection can be used. For oral administration, a compound of the present invention is formulated into conventional oral administration dosage forms such as capsules, tablets, and tonics. For injection, a compound is formulated in liquid solutions, preferably in physiologically compatible buffers such as Hank's solution or Ringer's solution. In addition, a compound can be formulated in a solid form and redissolved or suspended immediately prior to use. Lyophilized forms can also be produced. Examples of systemic administrations by injection include intramuscularly, intravenously, intraperitoneally and subcutaneously.

Administration also can be by transmucosal or transdermal means. For transmucosal or transdermal administration, penetrants appropriate to the barrier to be permeated are used in the formulation. Such penetrants are generally known in the art, and include, for example, for transmucosal administration, bile salts and fusidic acid derivatives. In addition, detergents may be used to facilitate permeation. Transmucosal administration also can be achieved, for example, by using nasal sprays or suppositories.

Administration of a compound of the present invention can be achieved by any means which transports the compound to the airways and/or lungs of a mammal, including a human patient. In a preferred embodiment, a compound is administered by generating an aerosol comprised of respirable particles, comprising said compound. Delivery is achieved by animal or patient inhalation of the respirable particles. The respirable particles can be liquid or solid and, optionally, can contain other therapeutic ingredients.

For topical administration, the molecules of the invention are formulated into ointments, salves, gels, or creams, as is generally known in the art.

Generally, a therapeutically effective amount for a human patient is between about 10 nmole and 3 mmole of the compound, preferably 1 μ mole to 1 mmole. A therapeutically effective amount for a non-human mammal is between about 0.01 and 50 mg/kg, preferably 0.01 and 20 mg/kg. Optimization of the timing and dosage of a disclosed compound is by convention adapted to, among other things, the particular characteristics of the patient or the non-human mammal and the nature and extent of the disease state, and the EC50 or IC50 of the compound. Such adaptations are routine and do not require abnormal experimentation or skill in the art.

In accordance with yet another aspect of the present invention, there is provided a kit suitable for treating CCR-3 mediated diseases in a patient, comprising a pharmaceutical

composition comprising one or more compounds of the present invention, reagents to effect administration of the pharmaceutical composition to the patient and instruments to effect administration of the pharmaceutical composition to the patient. Examples of such instruments include, but are not limited to application devices, such as syringes or inhalers.

- 5 In yet another embodiment, the claimed compounds are useful for treatment and/or prevention of rheumatoid arthritis. The treatment includes, but not limited to, administration of the claimed compounds through subcutaneous, intradermal, intramuscular, intraperitoneal, intravascular, and intracranial injections to human or other mammalian animal bodies.

SYNTHESIS OF ACTIVE COMPOUNDS

5 Example 1. Synthesis of N-Phenylcarbamoyl-N'-[2-(4-chlorophenyl)ethyl]-N'-ethyl-1,3-diaminopropane (Compound 1)

The following synthesis is depicted in Scheme 1.

Step 1: To a mixture of 2-(4-chlorophenyl)ethylamine (1.56 g, 10 mmol) and potassium carbonate (2.8 g, 20 mmol) in CH₃CN (50 ml) was added N-(3-
10 bromopropyl)phthalimide (3.0 g, 11 mmol). The mixture was refluxed under stirring for 16 h, and then filtered. The filtrate was concentrated under vacuum to dryness, and the residue was chromatographed on silica gel (eluting with 2.5% methanol/chloroform) to afford N-[3-[2-(4-chlorophenyl)ethylamino]propyl]phthalimide (2.28 g, 67%): MS(FD) m/e 343 [M+H]⁺; ¹H NMR (400 MHz, CDCl₃) δ 7.84 (m, 2H), 7.71 (m, 2H), 7.24 (d, J = 8.3
15 Hz, 2H), 7.11 (d, J = 8.3 Hz, 2H), 3.74 (d, J = 6.8 Hz, 2H), 2.82 (t, J = 6.8 Hz, 2H), 2.73 (t, J = 6.8 Hz, 2H), 2.66 (t, J = 6.8 Hz, 2H), 1.84 (m, 2H).

Step 2: To a mixture of N-[3-[2-(4-chlorophenyl)ethylamino]propyl]phthalimide (2.28 g, 6.65 mmol) and potassium carbonate (1.8 g, 13 mmol) in CH₃CN (50 ml) was added ethyl iodide (1.6 ml, 20 mmol). The mixture was stirred at 70 °C for 16 h, and then
20 filtered. The filtrate was concentrated under vacuum to dryness, and the residue was chromatographed on silica gel (eluting with 2% methanol/chloroform) to afford N-[3-[[2-(4-chlorophenyl)ethyl](ethyl)amino]propyl]phthalimide (1.41 g, 57%): MS(ES⁺) m/e 371 [M+H]⁺; ¹H NMR (400 MHz, CDCl₃) δ 7.84 (m, 2H), 7.71 (m, 2H), 7.23 (d, J = 8.5 Hz, 2H), 7.11 (d, J = 8.5 Hz, 2H), 3.71 (t, J = 7.3 Hz, 2H), 2.66 (m, 4H), 2.57 (m, 4H),
25 1.83 (m, 2H), 1.00 (t, J = 7.1 Hz, 3H).

Step 3: To a solution of N-[3-[[2-(4-chlorophenyl)ethyl](ethyl)amino]propyl]-phthalimide (1.41 g, 3.8 mmol) in EtOH (20 ml) was added a solution of hydrazine monohydrate (1.5 g, 30 mmol) in EtOH (5 ml). The solution was stirred at RT for 4h, and then filtered. The filtrate was concentrated under vacuum to dryness. After adding water,

30 Example 6. Synthesis of Active Compounds by Solid Phase Synthesis

The following synthesis is depicted in Scheme 6.

Step 1: *Reductive amination of the linker to the resin.* Novabiochem 2-(4-formyl-3-methoxy)phenoxyethyl polystyrene resin (0.5 mmol/g, 100g, 50 mmol) was added to a 500 ml erlenmyer flask. 3-Chloropropylamine hydrochloride (35.03g, 0.3 mole), 100 ml of 1% HOAc in DMF, and DIEA (53 ml, 0.3 mole) were added to the flask. The reaction
5 mixture was stirred for one hour, NaBH(OAc)₃ (0.3 mole) was added and the reaction was stirred for four hours.

The reaction mixture was poured into a 1000 ml sintered glass funnel and the solvent was removed by vacuum. DMF (500 ml) was added and the solution was mixed thoroughly for five minutes. A vacuum again removed the solvent. This wash process was
10 repeated two times. The resin was then washed in this manner three times with MeOH, three times with DCM, and three times with MeOH. The final resin was dried under a vacuum until constant weight.

Step 2: *Protection of linker.* The resin prepared above (30g, 15mmole) was placed into a 250 ml roundbottom flask. To this flask, DCM was added until a thick slurry was
15 obtained. DIEA (31.3 ml, 90 mmole) was added followed by the p-nitrobenzylchloroformate, which was added in 5g batches as a solid (19.4g, 45 mmole) while being stirred magnetically. The reaction was stirred for two hours. The reaction mixture was poured into a 1 L sintered glass funnel and a vacuum removed the solvent. The resin was resuspended in DCM and mixed thoroughly for five minutes before the solvent
20 was again removed. This was repeated two more times with DCM, and three times with MeOH. The resin was dried under a vacuum until constant weight.

Step 3: *Displacement of chlorine by amine.* The protected resin prepared above was transferred to a 96 well polyfiltronics plate (80mg, 0.04 mmole per well). The plate was placed onto a vacuum block and the resin was washed into their wells with DMSO.
25 The solvent was removed by vacuum. The plate was transferred onto a clamp and the bottom was sealed. To each of the wells with resin, a solution of TBAI (300 µl, 0.16 M) in DMSO and amine (R1-NH₂, 0.26 mmole) were added. The plate was sealed from the top and placed into an oven at 80 °C for 48 hours.

The plate was unclamped and placed onto the vacuum block where the solvent was
30 removed by vacuum. The plate was placed over a catch tray and each well with resin received roughly 1.5ml of DMSO each with a squirt bottle. The solvent was allowed to drain by gravity, then the remaining solvent was removed by vacuum. This was repeated

two more times with DMSO, three times with MeOH, three times with DCM, and three more times with MeOH. The plate was dried under a vacuum.

Step 4: *Reductive amination of secondary amine.* The plate was placed onto the vacuum block and the resin was washed down with a solution of 30% EtOH in DMF. The solvent was removed with a vacuum. The plate bottom was sealed with the clamp and the 30% EtOH in DMF (300 μ l) was added to each well with resin. Aldehydes (R2-CHO, 0.2 mmole) were added to their respective wells. The plate was sealed from the top and shaken for 2 hours. The plate was unclamped from the top and BAP (0.2 mmole) was added to each of the wells with resin. The plate was then resealed and shaken for 48 hours. The plate was unclamped and a vacuum removed the solvent. Each well was washed three times with DMF, three times MeOH, and three times DCM.

Step 5: *Deprotection of the p-nitrobenzyl carbamate.* A solution of SnCl₂ dihydrate in DMF (2.0 M) was prepared. The plate was again clamped and to each of the wells with resin, this solution was added (0.5 ml). The top of the plate was sealed and was allowed to stand overnight. The plate was unclamped, and washed two times with DMF. This deprotection was repeated a second time. The final wash solvents were three times DMF, three times MeOH, three times DMF, two times MeOH, then three times DCM.

Step 6: *Acylation of linker.* To the deprotected plate, a solution of DIEA in THF (150 μ l, 1.2 M) was added to all wells containing resin. These wells each received the respective isocyanates (R3-NCO, 0.09 mmole) in THF (150 μ l). The plate was sealed and allowed to stand for three hours. The plate was unclamped and washed with the following solvents: three times DCM, three times MeOH, three times DMF, three times MeOH, then three times DCM. The plate was dried under a vacuum.

Step 7: *Isolation of Final Products.* The dried plate was placed into the HCl gas cleavage apparatus. The system was flushed with nitrogen for ten minutes followed by a 10 minute flush with HCl gas. The system was sealed and the plate was allowed to sit for one hour in HCl gas. The system was recharged after the hour and the plate was allowed to sit for an additional hour. The system was flushed with nitrogen for ten minutes and the plate was removed. The plate was placed on a tarred 2 ml deepwell plate and the resin treated with a DCM wash (300 μ l). The solvent was allowed to drain by gravity and was followed by a MeOH wash (300 μ l). The process was repeated with a DCM and two MeOH washes. The collected filtrate was left out to dry overnight. The final material was placed into a

desiccator and was dried under a vacuum. The dried plate was weighed and the yield calculated; each well had an average weight of 12 mg.

Example 22. Evaluation of CCR-3 Inhibition Using a Calcium Mobilization Assay

The CCR-3 inhibitory activity of the disclosed compounds was determined by measuring the inhibition of eotaxin-induced calcium mobilization using the assay described below. Compounds 93-162 used in this assay were synthesized by using the method described in Example 6, and Compounds 168-170 were synthesized by using the method described in Example 6 except for the use of isothiocyanates instead of isocyanates in step 6.

CCR-3 transfectant cells (CCR3/HEK293) were isolated and resuspended with assay buffer (20 mM HEPES, 125 mM NaCl, 5 mM KCl, 0.5 mM glucose, 1 mM CaCl₂, 1 mM MgCl₂, 0.1 % BSA). After washing CCR3/HEK293 cells with assay buffer, cells were loaded with Fura-2/AM in assay buffer for 1 hour at room temperature. Cells were washed and resuspended with assay buffer at 5 x 10⁶ cells/ml in assay buffer, and placed in a tissue culture plate (Falcon, no. 3296). Test compounds dissolved in DMSO were added to the wells, followed by eotaxin (10 nM at final concentration). Cells were excited at 340 nm and 380 nm in a fluorimeter (ARGUS50, FDSS2000, Hamamatsu Photonics) and the relative ratio of the fluorescence emitted at 510 nm was recorded. For a control, DMSO without a test compound was added. Intracellular calcium mobilization was calculated as described in Krogel C. *et al.*, *FEBS Let.* (1989) 243, 41-46.

The results shown in Table 2a and Table 2b indicate that the disclosed compounds inhibit calcium mobilization.

Example 23. Evaluation of Eotaxin-induced Chemotaxis of CCR-3 Transfectant Cell

The inhibitory activity of the compounds against eotaxin-induced chemotaxis was determined by measuring the inhibition of migration of CCR-3 transfectant cells (CCR3/U937), using a minor modification of the method described by Ohashi, H. *et al.*, *Int Arch Allergy Immunol.* (1999) 118, 44-50. CCR-3 transfectant cells were grown in RPMI1640 medium containing 10% fetal calf serum (FCS) and Geneticin 418 (0.8 mg/ml). For the assay, CCR-3 transfectant cells were isolated and resuspended at 1×10^7 cells/ml in assay medium (RPMI 1640 medium containing 0.1 % bovine serum albumin (BSA)). The chemotaxis assay was performed in a 24-well culture plate. Human eotaxin suspended in assay medium was added to the wells at 1×10^{-9} M along with test compounds at various concentrations. For a positive control, eotaxin was added to the wells without a test compound, and for a negative control, neither eotaxin nor a test compound was added to the wells. Chemotaxicell (Kurabo Co., Ltd.) having 5 micrometers pore size were inserted into each well and 100 micro liters of CCR-3 transfectant cells suspension were added to the top chamber. The plates were incubated at 37 °C for 1 hour. After incubation, migrated cells in lower wells were diluted and counted by particle size distribution analyzer (CDP-500, Sysmex Co., Ltd.).

The results shown in Table 3a, 3b, 3c and 3d indicate that the disclosed compounds inhibit eotaxin-induced chemotaxis.

Example 24. Evaluation of Eotaxin-induced Chemotaxis of Eosinophils

The inhibitory activity of the compounds against eotaxin-mediated chemotaxis of human-derived eosinophils was determined by the assay described below.

Eosinophils were prepared from culture of human cord blood mononuclear cells as described by Ohashi, H. *et al.*, *Int Arch Allergy Immunol.* (1999) 118, 44-50. For the assay, eosinophils were resuspended at 1×10^7 cells/ml in assay medium (RPMI 1640 medium containing 0.1 % bovine serum albumin (BSA)). The chemotaxis assay was performed in a 24-well culture plate. Human eotaxin suspended in assay medium was added into wells at 1×10^{-9} M with test compounds at various concentrations. For a positive control, eotaxin was added without a test compound, and for a negative control, neither eotaxin nor a test compound was added to the wells. Chemotaxicell (Kurabo Co., Ltd.) having 5 micrometers pore size were inserted into each well and 100 microliters of eosinophil suspension were added to the top chamber. The plates were incubated at 37 °C for 1 hour. After incubation, migrated cells in lower wells were diluted and counted by particle size distribution analyzer (CDP-500, Sysmex Co., Ltd.).

The results shown in Table 4 indicate that the disclosed compounds inhibit eotaxin-induced chemotaxis in cultured eosinophils.

Example 25. Use of an Urea Derivative to treat a CCR-3 Mediated Disease

A patient suffering from asthma is administered N-Phenylcarbamoyl-N'-[2-(4-chlorophenyl)ethyl]-N'-ethyl-1,3-diaminopropane (Compound 1). Approximately 1 mmole
5 of the compound is administered to the patient via inhalation of an aerosol comprising compound 1. The amount of compound administered should be between 0.01 and 20 mg/kg of the patient's weight.

Example 26. Suppression of Type II Collagen-induced Arthritis in Mice by
10 Compound No. 60 and Compound No. 298

The inhibitory effects of Compound No. 60 (CPD No.60) and Compound No. 298 (CPD No. 298) on collagen-induced arthritis were evaluated in mice.

Male DBA/1 mice were purchased from Japan Charles River Inc. (Kanagawa, Japan) and used at 5 week of age. Mice were immunized intradermally at the base of the
15 tail with mixture of 100 µg of bovine type II collagen (Collagen Gijyutsu-Kenshukai, Japan) and 100 µg of *Mycobacterium tuberculosis* H37Ra (Difco, Detroit, MI) in incomplete Freund's adjuvant at the base of the tail, and then boosted 21 days later with same emulsion. The compound to be studied (20 mg/kg per day) was administered subcutaneously starting at 2nd immunization. In the control experiment, control vehicle
20 (10% DMSO and 10% Cremophor EL in saline) was administered instead of the compound to be studied. Clinical scoring for each paw was assessed by reference to the following scale: 0=normal, 1=swelling and/or erythema of one toe, 2=swelling and/or erythema of two or more toes, 3=swelling and erythema of the entire paw, 4=complete swelling and erythema of the entire paw and incapacity to bend the ankle. Clinical score for the whole
25 animal was expressed as the cumulative value for all paws, with a maximum of 16. Each group consists of 10 animals.

The inhibitory effects of Compound No. 60 and Compound No. 298 on collagen-induced arthritis were shown in Figure 1A and 1B, respectively. A marked prevention in clinical score was observed by administration of Compound No. 60 or Compound No. 298,
30 as opposed to administration of control vehicle.

Example 27. Suppression of Airway Hyperreactivity and Eosinophil Infiltration in Bronchoalveolar Lavage Fluid (BALF) by Compound No. 298

Male BALB/c mice were immunized by an intraperitoneal injection of 10 μ g OVA adsorbed to 1 mg aluminum hydroxide gel (alum). A booster injection of the same
5 dose of alum-adsorbed OVA was given 5 days later. Unimmunized control mice received saline.

Twelve days after primary immunization, both the immunized and unimmunized mice were exposed to aerosolized antigen. Aerosolization of OVA was performed using a nose-only aerosol chamber adapted for mice. Animals were exposed for 10 minutes to
10 5 mg/ml OVA aerosolized by an ultrasonic nebulizer (NE-U12, Omron, Tokyo, Japan) driven by a vacuum pump. The antigen bronchoprovocation was repeated on day 16 and day 20 under the same conditions. Compound No. 298 (CPD No. 298) was dissolved in saline containing 2 % DMSO and 2 % Cremophore and administered intraperitoneally for 9 days, starting on the first day of antigen inhalation.

15 Twenty-four hours after the final aerosol exposure, bronchoconstriction was measured by the overflow method of Konzett and Rössler. Mice were anesthetized by an intraperitoneal injection of sodium pentobarbitone (50 mg/kg), and the tracheas were surgically exposed, cannulated, and connected to a rodent ventilator (Model 683, Harvard Apparatus, South Natick, MA) and a bronchospasm transducer (Model 7020, Ugo Basile,
20 Comerio-Varese, Italy). Animals were mechanically ventilated with air at 60 strokes/min with a stroke volume of 0.6 ml. A paralytic agent, pancuronium bromide, 0.1 mg/kg, was administered to eliminate spontaneous respiration. After a stable baseline airway pressure was established, acetylcholine chloride was injected intravenously in a volume of 1 μ l/g of mouse per dose, starting with 31.3 μ g/kg, and increasing the concentration two-fold for
25 each subsequent dose. Bronchoconstriction was recorded on a flatbed recorder (Model FBR-252A, TOA Electronics Ltd., Tokyo, Japan). Bronchoconstriction (%) represent the respiratory overflow volume provoked by acetylcholine as a percentage of the maximal overflow volume (100%) obtained by totally occluding the tracheal cannula. See Figure 2A. Inhibition of bronchoconstriction provoked by acetylcholine (Murine Asthma Model)
30 by Compound No. 298 was shown in Figure 2A. In some experiments, airway reactivity was expressed by the area under the dose-response curve (the curves in Figure 2A) of bronchoconstriction against the acetylcholine concentration. See Figure 2B.

Immediately after the measurement of airway reactivity to acetylcholine, BALF was collected by lavaging whole-lung three times with 0.7-ml aliquots of physiological saline containing 0.1% BSA via the tracheal cannula while gently massaging the thorax. The BALF recovered from one mouse was pooled, centrifuged, and the cells were resuspended
5 in 100 μ l saline containing 0.1% BSA. Cell numbers were determined using a hemocytometer and 2×10^4 cells were cytocentrifuged onto a glass slide. Cells were stained with Diff-Quik (International reagent, Kobe, Japan), and cell types were identified by morphological criteria. Two hundred cells were examined per slide for differential count. See Figure 2C. As shown in Figure 2C, Compound No. 298 (CPD No. 298) significantly
10 suppressed eosinophil infiltration to bronchoalveolar lavage fluid (BALF).
